

15 February 2022

DRILLING AND DEVELOPMENT UPDATE – MT ALEXANDER HIGH-GRADE NICKEL-COPPER SULPHIDE PROJECT**HIGHLIGHTS****First seismic hole MAD206 hits target:**

- MAD206 completed to 1,003.9m downhole to test seismic target S1
- Drill hole successfully intersected the Cathedrals Belt structure that hosts intrusive style mafic rocks at location predicted by seismic survey
- A review of drillhole data is underway to determine the source of the large seismic reflector represented by S1
- Drilling of other seismic targets continues with MAD207 in progress to test target S2

Additional seismic surveys planned following strong results from the initial survey:

- New north-south oriented lines are being designed for the Stricklands and Cathedrals Prospect areas where shallow high-grade nickel-copper sulphide discoveries remain open at depth
- East-west oriented seismic line is being designed for the Cathedrals Belt to optimise modelling of the plunge and down-dip variability of the structure

Stricklands starter mine proposal advances:

- Metallurgical programme is developing a flowsheet for the sequential flotation of copper then nickel to produce separate copper and nickel concentrates
- Testwork has been completed with final report pending including locked cycle metallurgical results for precious and platinum group metals
- Discussions underway for a pilot plant campaign using the XPS Mini Pilot Plant to optimise process development and progress concentrate marketing studies

Further Stricklands resource and exploration drilling planned:

- Additional resource drilling planned to test two strong electromagnetic (EM) conductors to the north-west of the Stricklands deposit
- EM conductors have geophysical properties consistent with massive sulphides – modelled with conductivity of 22,500 Siemens and 9,825 Siemens respectively – and have potential to add significant extensions to existing mineralisation
- Surface sampling underway of outcropping pegmatites as part of a Mt Alexander wide field mapping and geochemical programme to assess their lithium potential

Growth-focused Western Australian nickel company St George Mining Limited (ASX: **SGQ**) (“**St George**” or “**the Company**”) is pleased to provide an update on exploration and development activities at its flagship high-grade Mt Alexander Project, located in the north-eastern Goldfields.

John Prineas, St George Mining’s Executive Chairman, said:

“Our first drill hole to test a seismic target has intersected the Cathedrals Belt fault structure as modelled by the seismic data and also confirmed the presence of mafic rocks along the structure at depth.

“These deep-reaching structures are the control on mineralisation and our increased understanding of their orientation and location will be of great help with targeting the highly prospective but underexplored deeper areas of the mineralised intrusive system.

“Confirmation by MAD206 of the ability of the seismic survey to successfully and accurately map the framework of intersecting faults is encouraging for the ongoing exploration at Mt Alexander and will make our future programmes more effective.”

“Overall, we are strongly encouraged by these results and are assessing the completion of additional seismic lines over key exploration areas, including the Stricklands deposit where the seismic will assist to identify any continuation at depth of the high-grade shallow deposit.

“We have already identified two strong EM conductors outside the footprint of the Stricklands deposit that could materially increase the resource inventory, suggesting that there is more mineralisation at Stricklands that has not been detected by EM surveys to date.

“The unique geology at Mt Alexander means that there is no precedent for exploration here. But the five high-grade discoveries we have already made – including at Stricklands – drive our determination to press on to discover more nickel, copper and platinum group metals across what is a highly prospective and still underexplored project area.

“I am pleased that the metallurgical programme for Stricklands is nearing completion with a flowsheet to be provided for the potential commercial production of separate high-grade nickel and copper concentrates.

“We have already received preliminary approaches to secure the offtake from any potential mining operation at Stricklands, and will look at accelerating development studies with a pilot plant campaign through the XPS Mini Pilot Plant.

“We look forward to reporting on these exciting work programmes in due course.”

DRILLING OF SEISMIC TARGETS

Target S1: MAD206 was completed to a downhole depth of 1,003.9m to test seismic target S1. The hole intersected mainly granitic rocks with features observed as follows:

- **738.09m to end of hole (EOH)** – granite with weak to pervasive potassic alteration and epidote alteration. Where observed elsewhere in the Cathedrals Belt, granite with this kind of alteration is typically a marker of a nearby intrusive unit.
- **727m to 745m** – an extensive zone of low RQD (Rock Quality Designation Index) and intense potassic alteration that coincides with the seismic interpreted fault.

- **847m to 939.6m** – extensive fractures and faulted zones, indicative of an extensive fault system. Interpreted here to be the Cathedrals Belt fault zone.
- **939.6m to 940.08m** – intrusive mafic rocks. Aphanitic texture. No sulphides observed.

It is encouraging to see mafic rocks down-dip in the Cathedrals fault zone – this supports the prospectivity for mineralised intrusives to be present at depth.

The interval of intrusive rocks intersected in MAD206 is, however, not of a scale that could be the source of the large reflective anomaly at S1. The mafic intrusive that hosts mineralisation in the Cathedrals Belt is known to ‘pinch and swell’ along strike so there is potential for the intrusive to thicken again.

MAD206 lifted during drilling and at EOH was about 100m from the planned trajectory. S1 was modelled with a dip-extent of 450m and MAD206 was designed to drill the centre of the target. MAD206 did not depart from the planned azimuth. Despite the lifting of the hole, MAD206 is interpreted to have intersected S1 and tested the seismic reflector. One potential interpretation is that the faulted zone may be the source of the reflector.

RQD data for MAD206 confirms that the hole intersected fault structures as identified by the seismic survey. RQD is defined as the percentage of intact drill core pieces longer than 10 cm recovered during a single core run. RQD’s indicate the structural integrity of the rock being drilled and identify where rock failure is likely to occur. The measurement commonly highlights fault zones where RQD results are low (<50%).

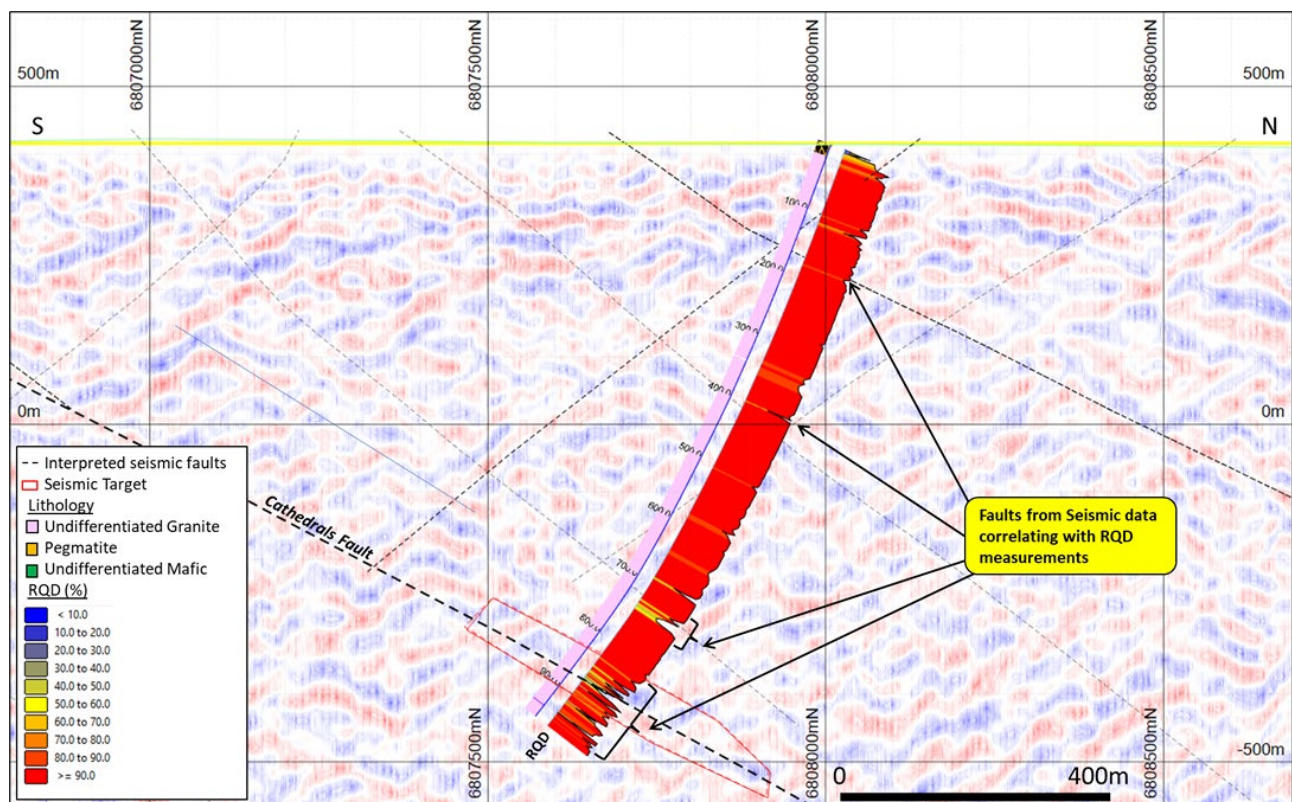

Figure 1 – cross section (looking west) against seismic data showing the trace of MAD206, RQD data for the hole and S1 (red outline).

A review of drill hole data is ongoing and will incorporate assay data once available as well as downhole EM (DHEM) survey data. A DHEM survey was completed in MAD206 to 934m downhole and is interpreted to have searched a radius of at least 50m around the hole. No strong EM anomalies were observed but the data will continue to be reviewed in conjunction with assay data.

A DHEM survey is planned to complete the remaining 70m of MAD206 in the coming weeks. MAD206 was completed in a way that readily allows daughter holes to be drilled as wedges to the existing hole – so there is still an opportunity to drill in the vicinity of MAD206 to further test this area.

Target S2: Drilling of S2 has now commenced. S2 is located in the Transits Belt structure, 1,100m north of the Cathedrals Belt.

The target is located approximately 350m below surface and has a dip extent of 400m; see Figure 2. The reflective properties of S2 are consistent with the reflective properties of the mineralised intrusive at Investigators that was observed in Line 1 of the seismic survey.

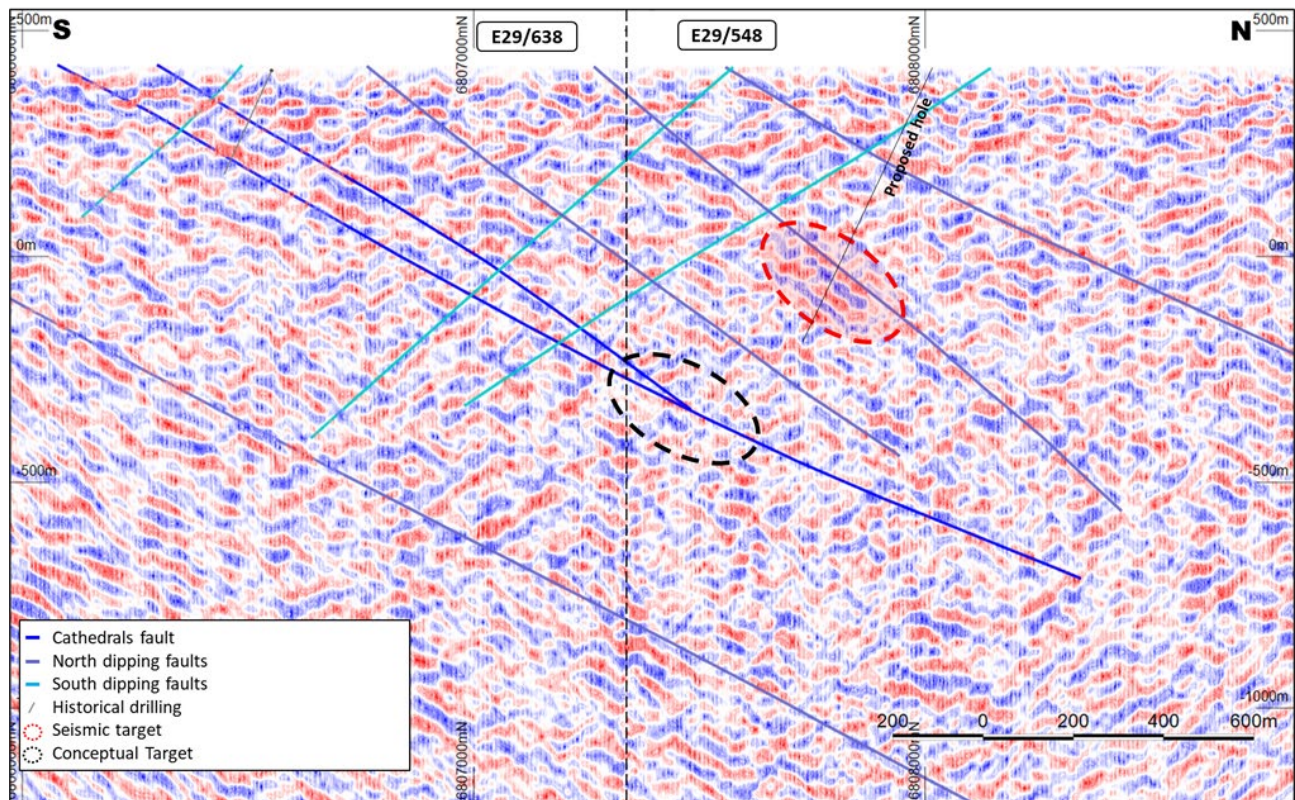

Figure 2 – cross section (looking west) showing the structures mapped by Line 2 in the seismic survey and the S2 target. The trace of the planned hole to test S2 is also shown.

For further details of the seismic targets S1 and S2, see our ASX Releases dated 1 December 2021 ‘*Seismic Results Unlock Standout Targets*’ and 8 December 2021 ‘*Seismic Delivers Another Standout Target at Mt Alexander*’.

ADDITIONAL SEISMIC SURVEY

MAD206 successfully intersected the Cathedrals Belt structure where predicted by the seismic data, confirming that the seismic data is effectively mapping the host structure(s) to the mineral system. This provides confidence that seismic is an effective targeting tool.

The initial survey comprised three north-south 2D seismic lines which covered an east-west strike of approximately 3km. Each line has provided a vertical plane of seismic data.

That survey did not cover the Stricklands and Cathedrals Prospects where shallow high-grade massive nickel-copper sulphides have been discovered with mineralisation open at depth.

New north-south survey lines are being designed for these areas. In addition, an east-west line is being designed along (or sub-parallel to) the Cathedrals Belt with a view to capture data on structure/mineralisation – this will better locate inflection points and other variability in the down-dip extent of the structure, which are likely to be associated with better mineralisation.

DRILL PROGRAMME

For approximately the past two weeks drilling has been carried out with a single shift only because of COVID-19 related issues. This reduced daily drill rates significantly. It is not clear when a second crew may become available for Mt Alexander. St George is working closely with our drill contractors to maximise drill rates during the programme.

Hole ID	Tenement	East	North	RL	EOH Depth	Target Depth	DIP	AZI	Target
MAD206	E29/548	231238	6808009	414	1003.9	850/950	-70	167	S1
MAD207	E29/548	230150	6808081	408	660	550	-65	173	S2
MAD208	E29/638	231238	6806942	421	390	320	-70	350	S3
MAD209	E29/548	231238	6808313	412	660	600	-70	170	S4
MAD210	E29/548	228751	6808926	408	360	330	-70	177	S5
MAD211	E29/638	232297	6806600	440	140	110	-65	135	EM- 22k S
MAD212	E29/638	232297	6806600	440	150	120	-65	106	EM- 10k S

Table 1 – drill hole details for the holes planned in the 2022 drill programme; MAD206 has been completed.

STRICKLANDS STARTER MINE

The metallurgical testwork programme underway with XPS in Canada is nearing completion. Sequential flotation of copper and nickel has been completed with locked cycle results for precious and platinum metals still pending.

The final report by XPS will include a flowsheet for production of separate nickel and copper concentrates. A pilot plant programme to optimise the flowsheet processing in a commercial operation is being considered using the XPS Mini Pilot Plant.

The Mini Pilot Plant requires only a small sample size, circa 300kg to 400kg, enabling the use of exploration drill core rather than mining samples.

Performance of the Mini Pilot Plant has been shown to be directly related to that of a full-scale plant, allowing the Mini Pilot Plant to be used as a tool for optimisation of flowsheet design and scale-up for commercial operation.

STRICKLANDS RESOURCE EXPANSION

EM conductors: Two strong EM conductors have been identified to the north-west of the Stricklands deposit.

They are located down-dip from the shallow high-grade deposit which includes exceptional mineralised intersections like MAD71 that returned assays of:

- 17.45m @ 3.01%Ni, 1.31%Cu, 0.13%Co and 1.68g/t Total PGEs from 37.45m**
including the massive sulphide zones of
- 5.3m @ 4.39%Ni, 1.45%Cu, 0.21%Co and 2.09g/t Total PGEs from 39.3m**
and
- 2.02m @ 5.05%Ni, 2.01%Cu, 0.21%Co and 3.31g/t Total PGEs from 50.6m**

Both conductors are interpreted to represent massive nickel-copper sulphides. One conductor is modelled with conductivity of 22,500 Siemens and is located 100m below surface. The other conductor is modelled with conductivity of 9,825 Siemens and is located 110m below surface.

The intrusive structure hosting the Stricklands mineralisation dips to the north-west, making these conductors ideally located for potential down-dip continuity of mineralisation. Drilling of the conductors will be prioritised following drilling of the seismic targets. Confirmation of the conductors as sulphide mineralisation is likely to add a material volume of mineralisation to the Stricklands deposit.

Figure 3 – map (against earth image) showing the envelope for the Stricklands deposit with the new EM conductors highlighted.

Pegmatite sampling: Significant outcropping pegmatites exist throughout the project tenure, particularly on the Mt Alexander greenstone belt.

A project-wide field mapping and rock chip sampling program has been initiated to assess the lithium bearing potential of these pegmatites. Mapping has commenced in the Stricklands and Jailbreak Prospect areas.

A number of rock chip samples have been collected at Stricklands and Jailbreak with assays pending. The lithium potential at Stricklands, if any, will be important in further considering mining proposals for Stricklands.

At the Jailbreak Prospect, pegmatites have been mapped for more than 250m trending east-northeast in the same stratigraphic package to the Timoni mine where Red Dirt Metals (ASX: RDT) recently announced a significant lithium discovery; see RDT ASX Releases dated 21 September 2021 “Mt Ida – A New Lithium Province” and 8 February 2022 “Maiden RC Lithium Results from Mt Ida”.

A further announcement on this exploration initiative will be made soon.

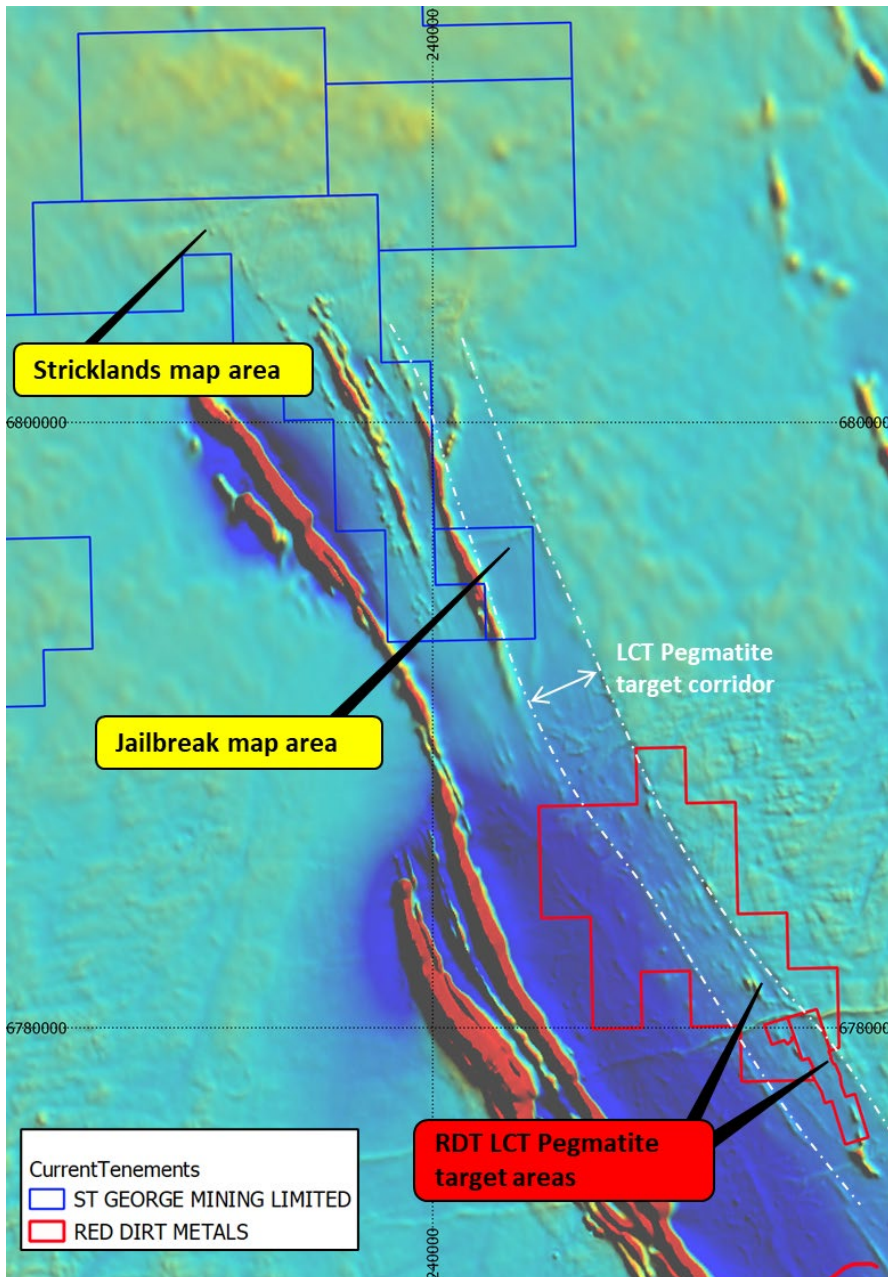

Figure 4 – regional map (against regional RTP magnetics) highlighting the continuation of the prospective lithium pegmatite corridor between the tenure of Red Dirt Metals and St George, and highlighting the areas being mapped/sampled by St George.

COVID-19:

St George continues to manage its operations in compliance with COVID-19 regulations issued by State and Commonwealth authorities. We proactively manage drilling and other field programmes to protect the health and safety of our team and service providers.

Border restrictions in Western Australia and elsewhere have impacted the movement of personnel for drill rig crews, which is constraining the availability of drill rigs. St George is in close contact with its drilling contractors to best manage access and continuity to drilling services.

About the Mt Alexander Project:

The Mt Alexander Project is located 120km south south-west of the Agnew-Wiluna Belt, which hosts numerous world-class nickel deposits. The Project comprises six granted exploration licences – E29/638, E29/548, E29/962, E29/954, E29/972 and E29/1041 – which are a contiguous package. A seventh granted exploration licence – E29/1093 – is located to the south-east of the core tenement package.

The Cathedrals, Stricklands, Investigators and Radar nickel-copper-cobalt-PGE discoveries are located on E29/638, which is held in joint venture by St George (75%) and Western Areas Limited (25%). St George is the Manager of the Project, with Western Areas retaining a 25% non-contributing interest in the Project (in regard to E29/638 only) until there is a decision to mine. All other Project tenements are owned 100% by St George.

Authorised for release by the Board of St George Mining Limited.

Competent Person Statement:

The information in this report that relates to Exploration Targets, Exploration Results, Mineral Resources or Ore Reserves for the Mt Alexander Project is based on information compiled by Mr Dave Mahon, a Competent Person who is a Member of The Australasian Institute of Mining and Metallurgy. Mr Mahon is employed by St George Mining Limited to provide technical advice on mineral projects, and he holds performance rights issued by the Company.

Mr Mahon has sufficient experience that is relevant to the style of mineralisation and type of deposit under consideration and to the activity being undertaken to qualify as a Competent Person as defined in the 2012 Edition of the 'Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves'. Mr Mahon consents to the inclusion in the report of the matters based on his information in the form and context in which it appears.

The following section is provided for compliance with requirements for the reporting of exploration results under the JORC Code, 2012 Edition.

Section 1 Sampling Techniques and Data

(Criteria in this section apply to all succeeding sections)

Criteria	JORC Code explanation	Commentary
Sampling techniques	<i>Nature and quality of sampling (eg cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</i>	<p><i>Diamond Core Sampling:</i> The sections of the core that are selected for assaying are marked up and then recorded on a sample sheet for cutting and sampling at the certified assay laboratory. Samples of HQ or NQ2 core are cut just to the right of the orientation line where available using a diamond core saw, with half core sampled lengthways for assay.</p> <p><i>RC Sampling:</i> All samples from the RC drilling are taken as 1m samples for laboratory assay. Samples are collected using cone or riffle splitter. Geological logging of RC chips is completed at site with representative chips being stored in drill chip trays.</p> <p><i>DHEM Surveying:</i> The surveys were conducted using the DigiAtlantis system and VTX-100 transmitter. The readings were recorded at 5m intervals with 1m infill down hole. The surveys used 400 x 400m loops orientated to magnetic north.</p> <p><i>Gravity Surveying:</i> A ground gravity survey was completed by Atlas Geophysics. The following primary instrumentation was used for acquisition of the data;</p> <ul style="list-style-type: none"> - Scintrex CG-5 Autograv Gravity Meter (accuracy <0.02 mGal) - CHC Nav i70+ GNSS Rover Receiver - CHC Nav i70+ GNSS Base Receiver - Garmin GPS receivers for navigation <p>Gravity surveys are used to detect density contrasts which may be related to the underlying lithology and rock types, alteration of minerals or mineralisation.</p> <p>Seismic: The surveys were conducted by Apex Geo Pty Ltd independent contractors using the Aram Aries 1 instrument with an accelerated weight drop and picked up by the sercel SM-24 Geophone sensors.</p>
	<i>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</i>	<p><i>RC Sampling:</i> Samples are taken on a one metre basis and collected using uniquely numbered calico bags. The remaining material for that metre is collected and stored in a green plastic bag marked with that specific metre interval. The cyclone is cleaned with compressed air after each plastic and calico sample bag is removed. If wet sample or clays are encountered then the cyclone is opened and cleaned manually and with the aid of a compressed air gun. A blank sample is inserted at the beginning of each hole, and a duplicate sample is taken every 50th sample. A certified sample standard is also added according to geology, but at no more than 1:50 samples.</p> <p>Geological logging of RC chips is completed at site with representative chips being stored in drill chip trays. Downhole surveys of dip and azimuth are conducted using a single shot camera every 30m, and using a downhole Gyro when required, to detect deviations of the hole from the planned dip and azimuth. The drill-hole collar locations are recorded using a hand-held GPS, which has an accuracy of +/- 5m. All drill-hole collars will be surveyed to a greater degree of accuracy using a certified surveyor at a later date.</p> <p><i>Diamond Core Sampling:</i> For diamond core samples, certified sample standards were added as every 25th sample. Core recovery calculations are made through a reconciliation of the actual core and the driller's records. Downhole surveys of dip and azimuth were</p>

Criteria	JORC Code explanation	Commentary
	<p><i>Aspects of the determination of mineralisation that are Material to the Public Report.</i></p> <p><i>In cases where 'industry standard' work has been done this would be relatively simple (eg 'reverse circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (eg submarine nodules) may warrant disclosure of detailed information.</i></p>	<p>conducted using a single shot camera every 30m to detect deviations of the hole from the planned dip and azimuth. The drill-hole collar locations are recorded using a hand-held GPS, which has an accuracy of +/- 5m.</p> <p><i>RC Sampling:</i> A 1m composite sample is taken from the bulk sample of RC chips that may weigh in excess of 40 kg. Each sample collected for assay typically weighs 2-3kg, and once dried, is prepared for the laboratory as per the Diamond samples below.</p> <p><i>Diamond Core Sampling:</i> Diamond core (both HQ and NQ2) is half-core sampled to geological boundaries no more than 1.5m and no less than 10cm. Samples less than 3kg are crushed to 10mm, dried and then pulverised to 75µm. Samples greater than 3kg are first crushed to 10mm then finely crushed to 3mm and input into the rotary splitters to produce a consistent output weight for pulverisation.</p> <p>Pulverisation produces a 40g charge for fire assay. Elements determined from fire assay are gold (Au), platinum (Pt) and palladium (Pd) with a 1ppb detection limit. To determine other PGE concentrations (Rh, Ru, Os, Ir) a 25g charge for nickel sulphide collect fire assay is used with a 1ppb detection limit.</p> <p>Other elements will be analysed using an acid digest and an ICP finish. These elements are: Ag, Al, As, Bi, Ca, Cd, Co, Cr, Fe, K, Li, Mg, Mn, Mo, Nb, Ni, P, Pb, S, Sb, Sn, Te, Ti, V, W, Zn. The sample is digested with nitric, hydrochloric, hydrofluoric and perchloric acids to effect as near to total solubility of the sample as possible. The sample is then analysed using ICP-AES or ICP-MS.</p> <p>LOI (Loss on Ignition) will be completed on selected samples to determine the percentage of volatiles released during heating of samples to 1000°C.</p>
Drilling techniques	<p><i>Drill type (eg core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (eg core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc).</i></p>	<p><i>Diamond Core Sampling:</i> The collars of the diamond holes were drilled using RC drilling down through the regolith to the point of refusal or to a level considered geologically significant to change to core. The hole was then continued using HQ diamond core until the drillers determined that a change to NQ2 coring was required.</p> <p>The core is oriented and marked by the drillers. The core is oriented using ACT Mk II electric core orientation.</p> <p><i>RC Sampling:</i> The RC drilling uses a 140 mm diameter face hammer tool. High capacity air compressors on the drill rig are used to ensure a continuously sealed and high-pressure system during drilling to maximise the recovery of the drill cuttings, and to ensure chips remain dry to the maximum extent possible.</p>
Drill sample recovery	<p><i>Method of recording and assessing core and chip sample recoveries and results assessed.</i></p> <p><i>Measures taken to maximise sample recovery and ensure representative nature of the samples.</i></p>	<p><i>Diamond Core Sampling:</i> Diamond core recoveries are recorded during drilling and reconciled during the core processing and geological logging. The core length recovered is measured for each run and recorded which is used to calculate core recovery as a percentage.</p> <p><i>RC Sampling:</i> RC samples are visually checked for recovery, moisture and contamination. Geological logging is completed at site with representative RC chips stored in chip trays.</p> <p><i>RC Sampling:</i> Samples are collected using cone or riffle splitter. Geological logging of RC chips is completed at site with representative chips being stored in drill chip trays.</p> <p><i>Diamond Core Sampling:</i> Measures taken to maximise core recovery include using appropriate core diameter and shorter barrel length through the weathered zone, which at Cathedrals and Investigators is mostly <20m and Stricklands <40m depth. Primary locations for core loss in fresh rock are on geological contacts and structural zones, and</p>

Criteria	JORC Code explanation	Commentary
		drill techniques are adjusted accordingly, and if possible, these zones are predicted from the geological modelling.
	<i>Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material.</i>	To date, no sample recovery issues have yet been identified that would impact on potential sample bias in the competent fresh rocks that host the mineralised sulphide intervals.
Logging	<i>Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies.</i>	Geological logging is carried out on all drill holes with lithology, alteration, mineralisation, structure and veining recorded.
	<i>Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc) photography.</i>	Logging of diamond core and RC samples records lithology, mineralogy, mineralisation, structures (core only), weathering, colour and other noticeable features. Core was photographed in both dry and wet form.
	<i>The total length and percentage of the relevant intersections logged.</i>	All drill holes are geologically logged in full and detailed litho-geochemical information is collected by the field XRF unit. The data relating to the elements analysed is used to determine further information regarding the detailed rock composition.
Sub-sampling techniques and sample preparation	<i>If core, whether cut or sawn and whether quarter, half or all core taken.</i>	Diamond Core Sampling: Diamond core was drilled with HQ and NQ2 size and sampled as complete half core to produce a bulk sample for analysis. Intervals selected varied from 0.3 – 1m (maximum) The HQ and NQ2 core is cut in half length ways just to the right of the orientation line where available using a diamond core saw. All samples are collected from the same side of the core where practicable. Assay preparation procedures ensure the entire sample is pulverised to 75 microns before the sub-sample is taken. This removes the potential for the significant sub-sampling bias that can be introduced at this stage.
	<i>If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry.</i>	RC samples are collected in dry form. Samples are collected using cone or riffle splitter when available. Geological logging of RC chips is completed at site with representative chips being stored in drill chip trays.
	<i>For all sample types, the nature, quality and appropriateness of the sample preparation technique.</i>	RC Sampling: Sample preparation for RC chips follows a standard protocol. The entire sample is pulverised to 75µm using LM5 pulverising mills. Samples are dried, crushed and pulverized to produce a homogenous representative sub-sample for analysis. A grind quality target of 90% passing 75µm is used.
	<i>Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples.</i>	Quality control procedures include submission of Certified Reference Materials (standards), duplicates and blanks with each sample batch. QAQC results are routinely reviewed to identify and resolve any issues. RC Sampling: Field QC procedures maximise representivity of RC samples and involve the use of certified reference material as assay standards, along with blanks, duplicates and barren washes. Diamond Core Sampling: Drill core is cut in half lengthways and the total half-core submitted as the sample. This meets industry standards where 50% of the total sample taken from the diamond core is submitted.

Criteria	JORC Code explanation	Commentary
	<p><i>Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling.</i></p>	<p>Duplicate samples are selected during sampling. Samples comprise two quarter core samples for Diamond Core. Duplicate RC samples are captured using two separate sampling apertures on the splitter.</p>
	<p><i>Whether sample sizes are appropriate to the grain size of the material being sampled.</i></p>	<p>The sample sizes are considered to be appropriate to correctly represent base metal sulphide mineralisation and associated geology based on: the style of mineralisation (massive and disseminated sulphides), the thickness and consistency of the intersections and the sampling methodology.</p>
<p>Quality of assay data and laboratory tests</p>	<p><i>The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total.</i></p>	<p>A 25-50gram sample will be fire assayed for gold, platinum and palladium, using a minimum detection value of 1ppb for gold is 1ppb and 0.5ppb for platinum and palladium.</p> <p>All other metals will be analysed using an acid digest and an ICP finish. The sample is digested with nitric, hydrochloric, hydrofluoric and perchloric acids to effect as near to total solubility of the sample as possible. The solution containing samples of interest, including those that need further review, will then be presented to an ICP-OES for the further quantification of the selected elements.</p> <p>Diamond core samples are analysed for Au, Pt and Pd using a 40g lead collection fire assay; for Rh, Ru, Os, Ir using a 25g nickel sulphide collection fire assay; and for Ag, Al, As, Bi, Ca, Cd, Co, Cr, Fe, K, Li, Mg, Mn, Mo, Nb, Ni, P, Pb, S, Sb, Sn, Te, Ti, V, W, Zn using a four acid digest and ICP-AES or MS finish. The assay method and detection limits are appropriate for analysis of the elements required.</p>
	<p><i>For geophysical tools, spectrometres, handheld XRF instruments, etc, the parametres used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.</i></p>	<p>DHEM: The surveys were conducted using the DigiAtlantis system and VTX-100 transmitter. The readings were recorded at 5m intervals with 1m infill down hole. The transmitter produced 96amps and recorded at a frequency of 0.5Hz.</p> <p>XRF: A handheld XRF instrument (Olympus Innov-X Spectrum Analyser) is used to systematically analyse the drill core and RC sample piles onsite. One reading is taken per metre, however for any core samples with matrix or massive sulphide mineralisation then multiple samples are taken at set intervals per metre. The instruments are serviced and calibrated at least once a year. Field calibration of the XRF instrument using standards is periodically performed (usually daily).</p> <p>The handheld XRF results are only used for preliminary assessment and reporting of element compositions, prior to the receipt of assay results from the certified laboratory.</p> <p>Gravity: A Scintrex CG-5 Autograv Gravity Meter was used for data acquisition which has an accuracy of <0.02 mGal</p> <p>Elevation information was captured using CHC Nav i70+ GNSS receivers with an accuracy of <2m.</p>
	<p><i>Nature of quality control procedures adopted (eg standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (ie lack of bias) and precision have been established.</i></p>	<p>Laboratory QAQC involves the use of internal lab standards using certified reference material (CRMs), blanks and pulp duplicates as part of in-house procedures. The Company also submits a suite of CRMs, blanks and selects appropriate samples for duplicates.</p> <p>Sample preparation checks for fineness are performed by the laboratory to ensure the grind size of 90% passing 75µm is being attained.</p>
<p>Verification of sampling and assaying</p>	<p><i>The verification of significant intersections by either independent or alternative company personnel.</i></p>	<p>Significant intersections are verified by the Company's technical staff.</p>

Criteria	JORC Code explanation	Commentary
	<i>The use of twinned holes.</i>	No twinned holes have been planned for the current drill programme.
	<i>Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols.</i>	Primary data is captured onto a laptop using acQuire software and includes geological logging, sample data and QA/QC information. This data, together with the assay data, is entered into the St George Mining central SQL database which is managed by external consultants.
	<i>Discuss any adjustment to assay data.</i>	No adjustments or calibrations will be made to any primary assay data collected for the purpose of reporting assay grades and mineralised intervals. For the geological analysis, standards and recognised factors may be used to calculate the oxide form assayed elements, or to calculate volatile free mineral levels in rocks.
Location of data points	<i>Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation.</i>	<p>Drill holes and MT/AMT stations have been located and pegged using a DGPS system with an expected accuracy of +/-5m for easting, northing and elevation.</p> <p>Downhole surveys are conducted using a single shot camera approximately every 30m or downhole Gyro during drilling to record and monitor deviations of the hole from the planned dip and azimuth. Post-drilling downhole gyroscopic surveys will be conducted, which provide more accurate survey results.</p> <p>The Gravity data was positioned using CHCi70+ DGPS receivers operating in kinematic mode.</p> <p>Seismic survey: all stations were located using NAVCOM DGPS survey equipment. Vibration source points readings were taken every 10m along the lines, with receiver nodes at 5m spacing along the lines for 1,944 data collection points and a total of 12 lineal km were traversed to collect the 2D Seismic data set</p>
	<i>Specification of the grid system used.</i>	The grid system used is GDA94, MGA Zone 51.
	<i>Quality and adequacy of topographic control.</i>	Elevation data has been acquired using DGPS surveying at individual collar locations and entered into the central database. A topographic surface has been created using this elevation data.
Data spacing and distribution	<i>Data spacing for reporting of Exploration Results.</i>	<p>The spacing and distribution of holes is not relevant to the drilling programs which are at the exploration stage rather than definition drilling.</p> <p>The gravity data was collected at 25m station spacings.</p>
	<i>Whether the data spacing and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied.</i>	The completed drilling at the Project is not sufficient to establish the degree of geological and grade continuity to support the definition of Mineral Resource and Reserves and the classifications applied under the 2012 JORC code.
	<i>Whether sample compositing has been applied.</i>	No compositing has been applied to the exploration results.
Orientation of data in relation to geological structure	<i>Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type.</i>	<p>The drill holes are drilled to intersect the modelled mineralised zones at a near perpendicular orientation (unless otherwise stated). However, the orientation of key structures may be locally variable and any relationship to mineralisation has yet to be identified.</p> <p>Seismic: Three north-south oriented lines approximately perpendicular to the strike of known host structures of the Cathedrals belt were completed. Lines were spaced an average of 1.2km apart. The length of lines were designed to allow imaging of deep structures to approximately 1.5km depths.</p>

Criteria	JORC Code explanation	Commentary
	<i>If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material.</i>	No orientation based sampling bias has been identified in the data to date.
Sample security	<i>The measures taken to ensure sample security.</i>	Chain of Custody is managed by the Company until samples pass to a certified assay laboratory for subsampling and assaying. The RC sample bags are stored on secure sites and delivered to the assay laboratory by the Company or a competent agent. When in transit, they are kept in locked premises. Transport logs have been set up to track the progress of samples.
Audits or reviews	<i>The results of any audits or reviews of sampling techniques and data.</i>	Sampling techniques and procedures are regularly reviewed internally, as is data. To date, no external audits have been completed on the drilling programme. Results of the Seismic dataset was processed and queried by Dayborageo Geophysical Pty Ltd. Interpretations were completed by Rock Solid Seismic Pty Ltd with assistance from SGQ geologists. Both are independent contractors engaged by St George Mining.

Section 2 Reporting of Exploration Results (Criteria listed in section 1 will also apply to this section where relevant)

Criteria	JORC Code explanation	Commentary
Mineral Tenement and Land Status	<i>Type, name/reference number, location and ownership including agreements or material issues with third parties including joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings.</i> <i>The security of the tenure held at the time of reporting along with any known impediments to obtaining a licence to operate in the area.</i>	The Mt Alexander Project is comprised of six granted Exploration Licences (E29/638, E29/548, E29/954, E29/962, E29/972 and E29/1041). Tenement E29/638 is held in Joint Venture between St George (75% interest) and Western Areas (25% interest). E29/638 and E29/548 are also subject to a royalty in favour of a third party that is outlined in the ASX Release dated 17 December 2015 (as regards E29/638) and the ASX release dated 18 September 2015 (as regards E29/548). No environmentally sensitive sites have been identified on the tenements. A registered Heritage site known as Willsmore 1 (DAA identification 3087) straddles tenements E29/548 and E29/638. All five tenements are in good standing with no known impediments.
Exploration Done by Other Parties	<i>Acknowledgment and appraisal of exploration by other parties.</i>	Exploration on tenements E29/638 and E29/962 has been largely focused on the discovery of komatiite-hosted nickel sulphides within the Mt Alexander Greenstone Belt. Exploration in the northern section of E29/638 (Cathedrals Belt) and also limited exploration on E29/548 has been for mafic/ultramafic intrusion related Ni-Cu-PGE sulphides. No historic exploration has been identified on E29/954 or E29/972. Mafic-Ultramafic intrusion related high grade nickel-copper-PGE sulphides were discovered at the Mt Alexander Project in 2008. Drilling was completed to test co-incident electromagnetic (EM) and magnetic anomalies associated with nickel-PGE enriched gossans in the northern section of current tenement E29/638. The drilling identified high grade nickel-copper mineralisation in granite-hosted and East-West orientated ultramafic units and the discovery was named the Cathedrals Prospect.
Geology	<i>Deposit type, geological setting and style of mineralisation</i>	The Mt Alexander Project is at the northern end of a western bifurcation of the Mt Ida Greenstones. The greenstones are bound to the west by the interpreted Ida Fault, a significant Craton-scale structure that marks the boundary between the Kalgoorlie Terrane (and Eastern Goldfields Superterrane) to the east and the Youanmi Terrane to the west. The Mt Alexander Project is prospective for further high-grade nickel-mineralisation (both komatiite and mafic-ultramafic intrusive hosted) and also precious metal mineralisation (i.e. orogenic gold) that is

Criteria	JORC Code explanation	Commentary
		typified elsewhere in the Yilgarn Craton.
Drill hole information	<p>A summary of all information material to the understanding of the exploration results including tabulation of the following information for all Material drill holes:</p> <ul style="list-style-type: none"> • Easting and northing of the drill hole collar • Elevation or RL (Reduced Level – elevation above sea level in metres) of the drill hole collar • Dip and azimuth of the hole • Down hole length and interception depth • Hole length 	Drill hole collar locations are shown in the maps and tables included in the body of the relevant ASX releases.
Data aggregation methods	<p>In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (e.g. cutting of high grades) and cut-off grades are usually Material and should be stated.</p>	<p>Reported assay intersections are length and density weighted. Significant intersections are determined using both qualitative (i.e. geological logging) and quantitative (i.e. lower cut-off) methods.</p> <p>For massive sulphide intersections, the nominal lower cut-off is 2% for either nickel or copper. For disseminated, blebby and matrix sulphide intersections the nominal lower cut-off for nickel is 0.3%.</p>
	<p>Where aggregated intercepts incorporate short lengths of high grade results and longer lengths of low grade results, the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail.</p>	<p>Any high-grade sulphide intervals internal to broader zones of sulphide mineralisation are reported as included intervals.</p> <p>Any disseminated, matrix, brecciated or stringer sulphides with (usually) >1% nickel or copper on contact with massive sulphide mineralisation are grouped with the massive sulphides for calculating significant intersections.</p>
	<p>The assumptions used for any reporting of metal equivalent values should be clearly stated.</p>	<p>No metal equivalent values are used for reporting exploration results.</p>
Relationship between mineralisation widths and intercept lengths	<p>These relationships are particularly important in the reporting of exploration results. If the geometry of the mineralisation with respect to the drill hole angle is known, its nature should be reported. If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect.</p>	<p>Assay intersections are reported as down hole lengths. Drill holes are planned as perpendicular as possible to intersect the target EM plates and geological targets so downhole lengths are usually interpreted to be near true width.</p>
iagrams	<p>Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported. These should include, but not be limited to a plane view of drill hole collar locations and appropriate sectional views.</p>	<p>A prospect location map, cross section and long section are shown in the body of relevant ASX Releases.</p>
Balanced Reporting	<p>Where comprehensive reporting of all Exploration Results is not practical, representative reporting of both low and high grades and/or widths should be practiced to avoid misleading reporting of Exploration Results.</p>	<p>Reports on recent exploration can be found in ASX Releases that are available on our website at www.stgm.com.au:</p> <p>The exploration results reported are representative of the mineralisation style with grades and/or widths reported in a consistent manner.</p>
Other substantive exploration data	<p>Other exploration data, if meaningful and material, should be reported including (but not limited to): geological observation; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment;</p>	<p>All material or meaningful data collected has been reported.</p>

Criteria	JORC Code explanation	Commentary
	<p><i>metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances.</i></p>	
<p>Further Work</p>	<p><i>The nature and scale of planned further work (e.g. tests for lateral extensions or depth extensions or large – scale step – out drilling).Diagrams clearly highlighting the areas of possible extensions, including the main geological interpretations and future drilling areas, provided this information is not commercially sensitive.</i></p>	<p>A discussion of further exploration work underway is contained in the body of recent ASX Releases.</p> <p>Further exploration will be planned based on ongoing drill results, geophysical surveys and geological assessment of prospectivity.</p>
